Abstract

Method for compensation for a zero error in a Coriolis gyro

In a method for determination of the zero error of a Coriolis gyro (1'), the frequency of the oscillation is modulated, the output signal from a rotation rate control loop or quadrature control loop the Coriolis gyro **(1')** is demodulated synchronism with the modulation of the frequency of the read oscillation in order to obtain an auxiliary signal which is a measure of the zero error, a compensation signal is produced, and is passed to the input of the rotation rate control loop or quadrature control loop, with the compensation signal being controlled such that the magnitude of the auxiliary signal is as small as possible.
